Logic Functions over Galois Field GF(4)

Zensho NAKAO*

Abstract The elements of Galois field GF(4) are represented by four numerals {0, 1, 2, 3}; it is shown that all quaternary logic functions can be expressed in a sort of standard form as polynomial functions over GF(4); the two field operators of GF(4) are proposed as basic logic gates and are used as basic building blocks in the representation of the logic functions.

1. Introduction

In recent papers, Hachimine and Zukeran [HZ1] proposed a set of four-valued logic functions and demonstrated the completeness of the system; they also designed several quaternary logic circuits [HZ2].

The objective of this note is to show that how Galois field GF(4) (i.e., a finite field of four elements) can be used effectively to represent quaternary logic functions such as the ones studied in [HZ1, HZ2] in standard polynomial forms as was done in [N1, NZK].

2. Preliminaries

The set $A_2 = \{0, 1\}$ of two symbols 0, 1 can be made into a Boolean algebra by furnishing it with two binary operations \vee , \wedge and one unary operation $\bar{}$ which are defined by the following (truth) tables:

\vee	0	1
0	0	1
1	1	1

\wedge	0	1
0	0	0
1	0	1

x	\bar{x}
1	0
0	1

Table 1. Boolean operators

On A_2 , introduce two binary operations $+$, \cdot (or juxtaposition) by the (truth) tables:

$+$	0	1
0	0	1
1	1	0

\cdot	0	1
0	0	0
1	0	1

Table 2. Field operators

Received: October 31, 1984

*Department of Electronics Engineering and Computer Science

The algebraic operations now transform the structure on A_2 into that of Galois field GF(2). In fact, the Boolean algebraic structure $(A_2; \vee, \wedge, \bar{})$ and the field structure $(GF(2); +, \cdot)$ are related by the following transformation formulas:

$$(1) \quad \begin{array}{ll} x \wedge y = xy & xy = x \wedge y \\ x \vee y = x + y + xy & x + y = (x \wedge \bar{y}) \vee (\bar{x} \wedge y) \\ \bar{x} = x + 1 & \end{array}$$

Since GF(2) is a field, the operations in Table 2 define subtraction and division implicitly (namely, the charts are used backward), which are the operations impossible in the Boolean algebra A_2 . Also, it is known in field theory that we can always enlarge GF(2) to the extension field GF(2^n) (n is a natural number) which possesses exactly 2^n elements by adjoining a zero of some irreducible polynomial over GF(2).

In this note we let $n = 2$ and use GF(4) in studying $A_4 = \{0, 1, 2, 3\}$ with a quaternary logic structure. We can obtain GF(4) as the splitting field of the irreducible polynomial $p(x) = x^2 + x + 1$ over GF(2) by adjoining a solution α of $p(x) = 0$ in an extension field of GF(2). Since GF(4) is a two dimensional vector field over GF(2) with the base $\{1, \alpha\}$, where $\alpha^2 = \alpha + 1$, GF(4) has four elements $0, 1, \alpha, \alpha + 1$. For ease of reference and computation, we introduce two numerals 2 and 3, and let $\alpha = 2$ and $\alpha + 1 = 3$; we obtain the following addition and multiplication tables which are in fact the truth tables for the binary operations:

+	0	1	2	3
0	0	1	2	3
1	1	0	3	2
2	2	3	0	1
3	3	2	1	0

•	0	1	2	3
0	0	0	0	0
1	0	1	2	3
2	0	2	3	1
3	0	3	1	2

Table 3. Field operators

Recall that $(GF(4); +)$ is Klein's Viergruppe (hence, not cyclic), and that $(GF(4) - \{0\}; \cdot)$ is a cyclic group of order 3; both are Abelian (i.e., the tables are symmetric with respect to the main diagonal).

It is to be noted that there are quaternary logic functions on A_4 which cannot be expressed as standard Boolean functions, i.e., $(A_4; \vee, \wedge, \bar{})$ is not a complete system.

In the rest of the section, we quote the necessary results from Galois theory:

$$(2) \quad (x + y)^2 = x^2 + y^2 \quad \forall x, y \in GF(4)$$

$$(3) \quad x + x = 0 \quad \forall x \in GF(4)$$

Any function from a finite field into itself is known to be a polynomial function (use Lagrange's interpolation formula, for example); the following results give us the necessary formulas for our specific purpose [T]:

(4) If $f:GF(4) \longrightarrow GF(4)$ is a function, then f can be expressed in a polynomial form over $GF(4)$:

$$f(x) = a_0 + a_1x + a_2x^2 + a_3x^3,$$

where $a_0 = f(0)$, $a_i = \sum_{x \in GF(4)} x^{3-i}f(x)$, ($1 \leq i \leq 3$).

(5) If $f:GF(4) \times GF(4) \longrightarrow GF(4)$ is a mapping, then f can be realized as a polynomial mapping over $GF(4)$ in two variables:

$$f(x, y) = \sum_{0 \leq i, j \leq 3} a_{ij}x^i y^j,$$

where $a_{00} = f(0, 0)$, $a_{i0} = \sum_{x \in GF(4)} x^{3-i}f(x, 0)$, $a_{0i} = \sum_{y \in GF(4)} y^{3-i}f(0, y)$,

$a_{ij} = \sum_{x, y \in GF(4)} x^{3-i}y^{3-j}f(x, y)$, ($1 \leq i, j \leq 3$).

Note that in formulas (4) and (5) above, all calculations must be done in Galois field $GF(4)$, and also that (5) can be generalized to mappings

$$f:GF(4)^n \longrightarrow GF(4)$$

of $n (\geq 1)$ variables. With this rigid structure, we will be able to express all quaternary logic functions as polynomial functions on $GF(4)$ or $GF(4)^2$ (or $GF(4)^n$, if necessary) of total degree at most 6.

3. Translation of A_4 to $GF(4)$

It is proved that $(MIN, MAX, x^{(0,1)}, 1, 2)$ forms a complete system of quaternary logic functions in [HZ1]; we are going to express all those quaternary logic functions explicitly as polynomials over $GF(4)$, which is a consequence of the evident fact that $(GF(4); +, \cdot)$ is another complete system of quaternary logic functions. The BASIC programs used are included in the Appendix.

a. $MIN[x, y]$

Operation tables for the binary operators $MIN[x, y]$ and $MAX[x, y]$ are given below:

MIN	0	1	2	3
0	0	0	0	0
1	0	1	1	1
2	0	1	2	2
3	0	1	2	3

MAX	0	1	2	3
0	0	1	2	3
1	1	1	2	3
2	2	2	2	3
3	3	3	3	3

Table 4. MIN and MAX operators

By using formulas for a_{ij} in (5), we can obtain the following results:

$$(6) \quad \begin{aligned} a_{00} = a_{01} = a_{10} = a_{02} = a_{20} = a_{03} = a_{30} = a_{11} = a_{33} = 0 \\ a_{22} = 1, \quad a_{12} = a_{21} = a_{13} = a_{31} = 2, \quad a_{23} = a_{32} = 3 \end{aligned}$$

Thus we get a polynomial expression for $\text{MIN}[x, y]$:

$$(7) \quad \text{MIN}[x, y] = 2xy^2 + 2xy^3 + 2x^2y + 2x^3y + x^2y^2 + 3x^2y^3 + 3x^3y^2$$

By using (2) and collecting like terms, we can change $\text{MIN}[x, y]$ into a less formidable polynomial in elementary symmetric functions $(x + y)$ and (xy) :

$$(8) \quad \text{MIN}[x, y] = xy \{2(x + y) + 2(x + y)^2 + xy[1 + 3(x + y)]\}$$

b. $\text{MAX}[x, y]$

Computing similarly as in $\text{MIN}[x, y]$, we can derive the following results:

$$(9) \quad \begin{aligned} a_{00} = a_{02} = a_{20} = a_{03} = a_{30} = a_{11} = a_{33} = 0, \quad a_{23} = a_{32} = 3 \\ a_{01} = a_{10} = a_{22} = 1, \quad a_{12} = a_{21} = a_{13} = a_{31} = 2 \end{aligned}$$

Therefore, a polynomial expression for $\text{MAX}[x, y]$ is:

$$(10) \quad \text{MAX}[x, y] = x + y + 2x^2y + 2xy^2 + 2x^3y + 2xy^3 + x^2y^2 + 3x^3y^2 + 3x^2y^3$$

Rewriting the result above as a polynomial in $(x + y)$ and (xy) , we get:

$$(11) \quad \text{MAX}[x, y] = (x + y) + xy[2(x + y) + 2(x + y)^2 + xy + 3xy(x + y)]$$

c. $x^{(0,2)}$

The unary operator $x^{(0,2)}$ is defined by:

$$(12) \quad \begin{aligned} x^{(0,2)} &= 3 \text{ if } x \in \{0, 2\} \\ &= 0 \text{ otherwise} \end{aligned}$$

A truth table for the operator is given below:

x	0	1	2	3
$x^{(0,2)}$	3	0	3	0

Table 5. Truth table for $x^{(0,2)}$

Repeated applications of the formulas for a_i in (4) yield:

$$(13) \quad a_0 = 3, \quad a_1 = 2, \quad a_2 = 1, \quad a_3 = 0$$

Hence, we obtain a polynomial function for $x^{(0,2)}$:

$$(14) \quad x^{(0,2)} = 3 + 2x + x^2 = (1 + x)(3 + x)$$

Putting pieces obtained together, we demonstrated that the algebraic structure $(GF(4); +, \bullet)$ provides an effective method for deriving standard forms of the quaternary logic functions.

4. Other translations

For completeness of presentation, we include the polynomial formulas for the binary operator $NOR[x, y]$; the unary operators ${}^{(k)}x$ and $x^{(k)}$ which are discussed in [HZ2]. Their definitions follow:

$$(15) \quad NOR[x, y] = 3 + MAX[x, y]$$

$$(16) \quad {}^{(k)}x \equiv x + k \pmod{4}, \quad k = 0, 1, 2, 3$$

$$(17) \quad x^{(k)} = \begin{cases} 3 & \text{if } x = k \\ 0 & \text{otherwise} \end{cases} \quad k = 0, 1, 2, 3$$

Polynomial representations for the operators are given in the following:

$$(18) \quad \begin{aligned} NOR[x, y] &= 3 + MAX[x, y] \\ &= 3 + (x + y) + xy[2(x + y) + 2(x + y)^2 + xy + 3xy(x + y)] \end{aligned}$$

$$(19) \quad {}^{(k)}x = (x + k) + xk[3 + 2(x + k) + xk], \quad k = 0, 1, 2, 3$$

$$(20) \quad x^{(k)} = 3[1 + (x + k)^3], \quad k = 0, 1, 2, 3$$

5. Conclusions

We found that all quaternary logic functions of one or two variables can be realized as polynomial functions over Galois field $GF(4)$ in one or two variables of total degree at most 6. An obvious advantage for having polynomial expressions is that we can formally manipulate the elements of A_4 , i.e., $GF(4)$ with four arithmetic operations of $GF(4)$ itself as we normally do with the real (or complex) number field.

If we can design $(x + y)$ and (xy) as basic logic circuit elements*, then we can easily construct other circuits such as MIN , MAX , $x^{[0,2]}$, NOR , ${}^{(k)}x$ and $x^{(k)}$. For illustration, take MIN , MAX and $x^{[0,2]}$. We introduce two logic gate symbols for the operators $(x + y)$ and (xy) :

Figure 1. Circuit symbols for $(x + y)$ and (xy)

Then the following diagrams present one possible design for each function:

*The logic circuit elements were designed by Mr. Chotei Zukeran, Department of Electrical Engineering, Ryukyu University; and are included as Figures in the Appendix.

Figure 2. $\text{MIN}[x, y]$ gateFigure 3. $\text{MAX}[x, y]$ gateFigure 4. Logic gate for $x^{(0,2)}$

Some properties of quaternary logic functions over $GF(4)$ will be discussed further in the forthcoming paper [N2].
